Advanced Encryption Standard (AES)

Dr. Khalid A. Hafeez
Spring, 25

Reminder: Finite Field Arithmetic

- A field is a set in which we can do addition, subtraction, multiplication, and division without leaving the set
 - Division is defined with the following rule: $a / b = a (b^{-1})$
- An example of a finite field (one with a finite number of elements) is the set Z_p consisting of all the integers $\{0, 1, \dots, p - 1\}$, where p is a prime number and in which arithmetic is carried out modulo p
- If one of the operations used in the algorithm is division, then we need to work in arithmetic defined over a field
 - Division requires that each nonzero element have a multiplicative inverse
- For convenience and for implementation efficiency we would like to work with integers that fit exactly into a given number of bits with no wasted bit patterns
 - Integers in the range 0 through $2^n - 1$, which fit into an n -bit word
- The set of such integers, Z_2^n , using modular arithmetic, is **not a field**
 - For example, the integer 2 has no multiplicative inverse in Z_2^n , that is, there is no integer b , such that $2b \bmod 2^n = 1$
- A finite field containing 2^n elements is referred to as $GF(2^n)$
 - Every polynomial in $GF(2^n)$ can be represented by an n -bit number

Advanced Encryption Standard (AES) - Background

- 1997 ← call for proposal for AES by National Institute of Standards and Technology (NIST)
- Aug 1998 ← about 15 algorithm submitted
- Aug 1999 ← 5 Finalist selected
- Oct 2000 ← Rijndael (Belgium) was choose as the AES
- AES Operations: addition, multiplication, and division/inverse are performed over the finite field $GF(2^8)$
- Irreducible polynomial: $m(x) = x^8 + x^4 + x^3 + x + 1$

AES Encryption Process – Big Picture

- The input to the encryption and decryption algorithms is a single 128-bit block, depicted as a 4 * 4 square matrix of bytes
- The ordering of bytes within a matrix is by column.
 - The first 4 bytes will be put in the first column and so on
 - Example: Plaintext: 0123456789abcdeffedcba9876543210

01	89	fe	76
23	ab	dc	54
45	cd	ba	32
67	ef	98	10

i_{n_0}	i_{n_4}	i_{n_8}	$i_{n_{12}}$
i_{n_1}	i_{n_5}	i_{n_9}	$i_{n_{13}}$
i_{n_2}	i_{n_6}	$i_{n_{10}}$	$i_{n_{14}}$
i_{n_3}	i_{n_7}	$i_{n_{11}}$	$i_{n_{15}}$

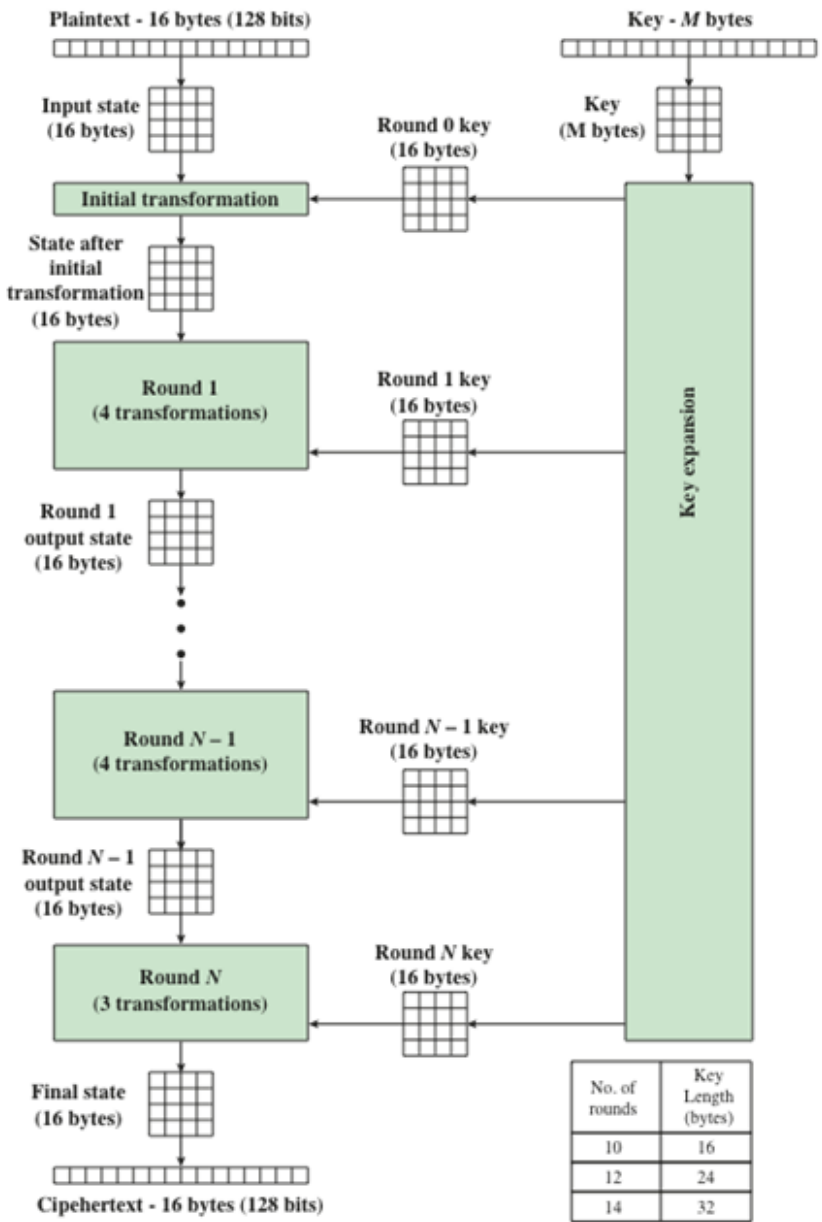

$s_{0,0}$	$s_{0,1}$	$s_{0,2}$	$s_{0,3}$
$s_{1,0}$	$s_{1,1}$	$s_{1,2}$	$s_{1,3}$
$s_{2,0}$	$s_{2,1}$	$s_{2,2}$	$s_{2,3}$
$s_{3,0}$	$s_{3,1}$	$s_{3,2}$	$s_{3,3}$

State Array

k_2	k_6	k_{10}	k_{14}
k_3	k_7	k_{11}	k_{15}

(b) Key and expanded key

AES Encryption Process – Big Picture

- AES Parameters

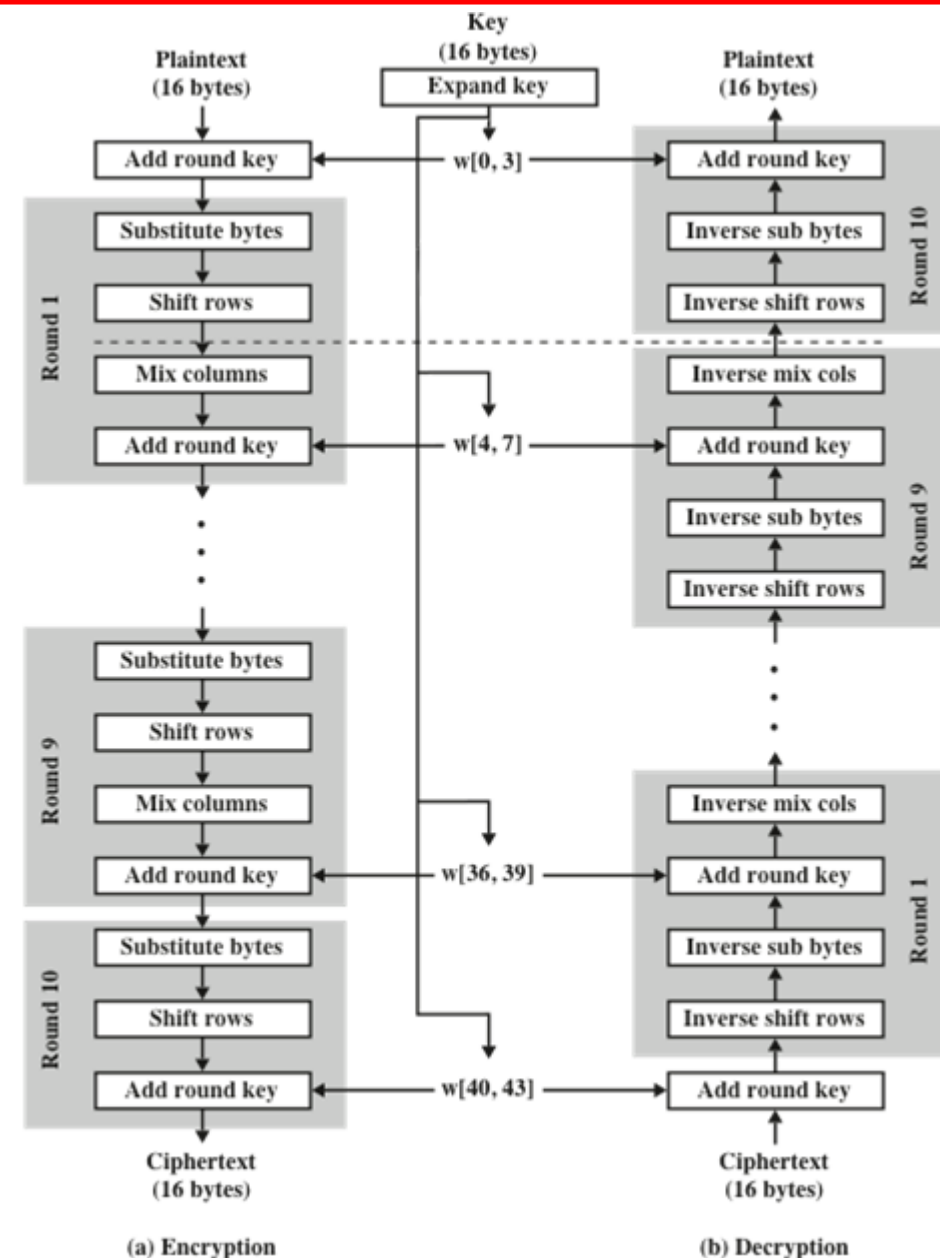

Key Size (words/bytes/bits)	4/16/128	6/24/192	8/32/256
Plaintext Block Size (words/bytes/bits)	4/16/128	4/16/128	4/16/128
Number of Rounds	10	12	14
Round Key Size (words/bytes/bits)	4/16/128	4/16/128	4/16/128
Expanded Key Size (words/bytes)	44/176	52/208	60/240

AES Encryption Process

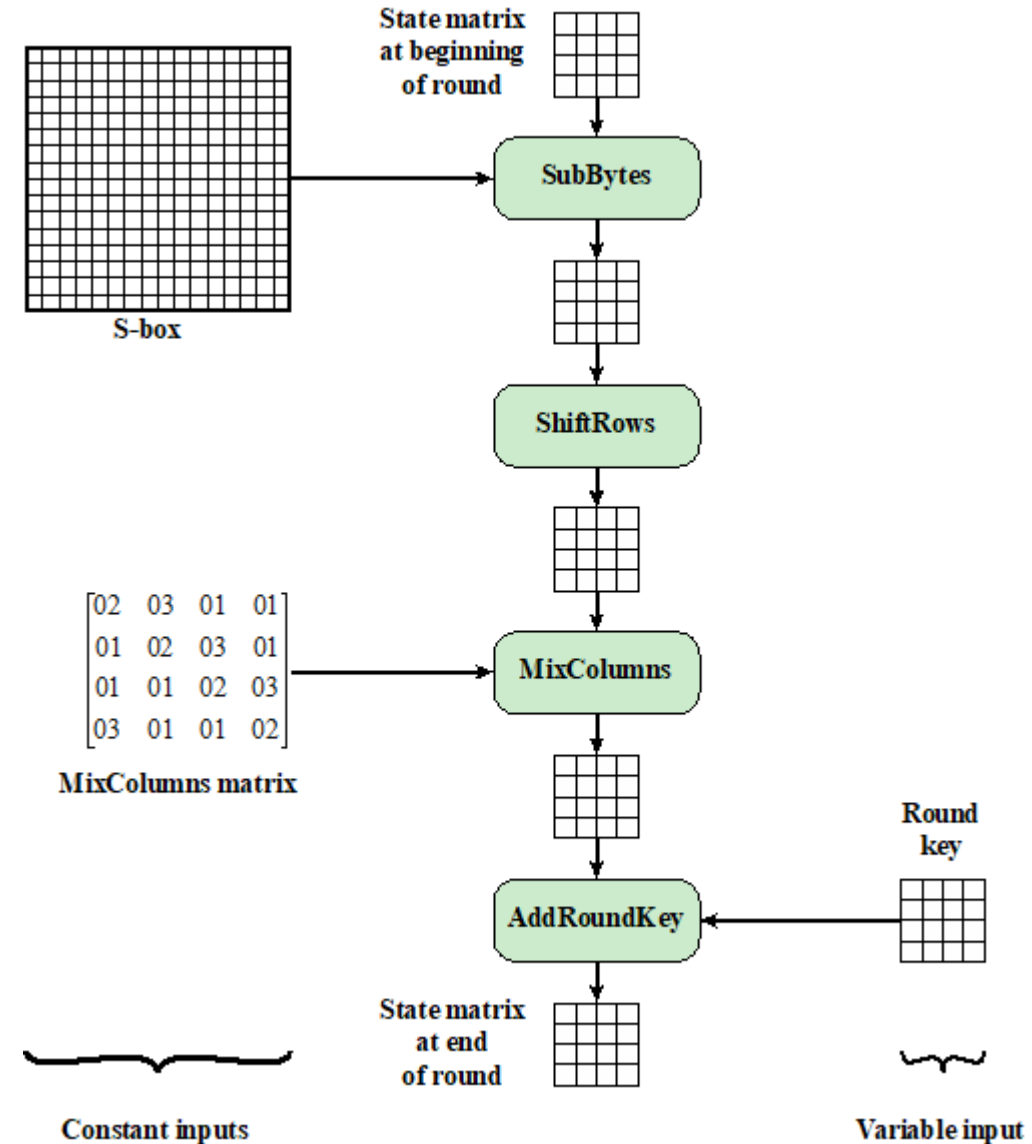

- **AES Encryption and Decryption – Detailed Structure**
- 10 rounds: the first 9 has 4 stages each and the 10th round has only 3 stages
- Processes the entire data block as a single matrix during each round using substitutions and permutation
- The key that is provided as input is expanded into an array of forty-four 32-bit words, $w[i]$
- The cipher begins and ends with an AddRoundKey stage
- Four different stages are used:
 1. **Substitute bytes** – uses an S-box to perform a byte-by-byte substitution of the block
 2. **ShiftRows** – a simple permutation
 3. **MixColumns** – a substitution that makes use of arithmetic over $GF(2^8)$
 4. **AddRoundKey** – a simple bitwise XOR of the current block with a portion of the expanded key

AES Encryption Process

- **In each round:**
- Can view the cipher as alternating operations of XOR encryption (AddRoundKey) of a block, followed by scrambling of the block (the other three stages), followed by XOR encryption, and so on
- Each stage is easily reversible
- The decryption algorithm makes use of the expanded key in reverse order, however the decryption algorithm is not identical to the encryption algorithm
- State is the same for both encryption and decryption
- Final round of both encryption and decryption consists of only three stages

AES - (1) Substitute bytes

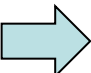

- leftmost 4 bits of the byte are used as a **row** value and the **rightmost 4 bits** are used as a **column** value
- Row and column values serve as indexes into the S-box to select a unique 8-bit output value

AES: S-Box Construction

1. Initialize the S-box with the byte values in ascending sequence row by row.
 - The first row contains {00}, {01}, {02}, ..., {0F};
 - The second row contains {10}, {11}, etc.; and so on.
 - Thus, the value of the byte at row y , column x is $\{yx\}$.
2. Map each byte in the S-box to its multiplicative inverse in the finite field $GF(2^8)$; the value {00} is mapped to itself.
3. Consider that each byte in the S-box consists of 8 bits labeled ($b_7, b_6, b_5, b_4, b_3, b_2, b_1, b_0$). Apply the following transformation to each bit of each byte in the S-box:

$$b'_i = b_i \oplus b_{(i+4) \bmod 8} \oplus b_{(i+5) \bmod 8} \oplus b_{(i+6) \bmod 8} \oplus b_{(i+7) \bmod 8} \oplus c_i$$

- where c_i is the i^{th} bit of byte c with the value $\{63\}_{16}$; that is, $(c_7c_6c_5c_4c_3c_2c_1c_0) = (01100011)$.
- **S-Box Rationale:**
 - The S-box is designed to be resistant to known cryptanalytic attacks
 - The design has a low correlation between input bits and output bits and the property that the output is not a linear mathematical function of the input
 - The nonlinearity is due to the use of the multiplicative inverse

(a) Calculation of byte at row y , column x of S-box

AES: S-Box Construction – Example

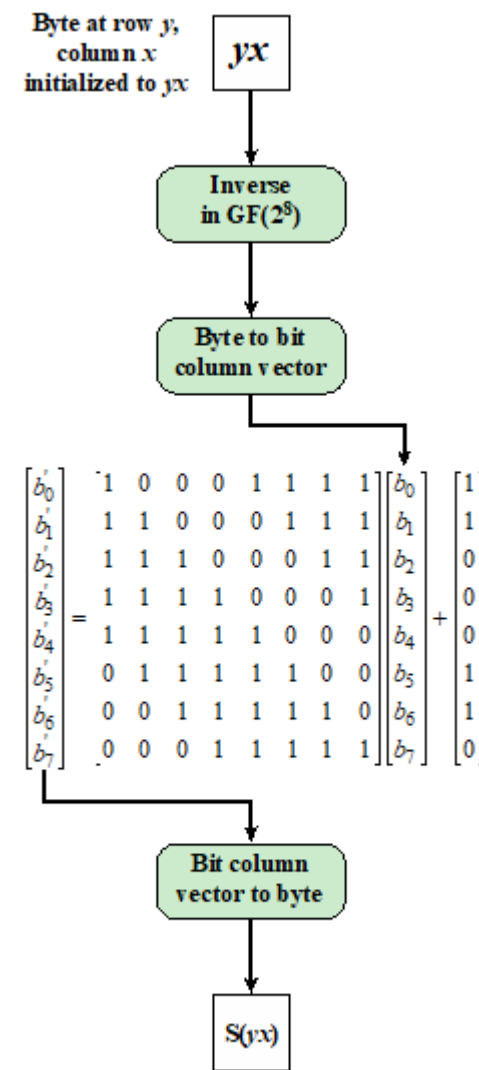

- Example:** As an example, consider the input value {95}. The multiplicative inverse in $GF(2^8)$ is $\{95\}^{-1} = \{8A\}$, which is 10001010

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} \oplus \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ 1 \\ 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 1 \\ 0 \end{bmatrix} \oplus \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 1 \\ 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 1 \\ 1 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

(a) Calculation of byte at row y , column x of S-box

AES: (2) ShiftRows Transformation

- Shift rows:

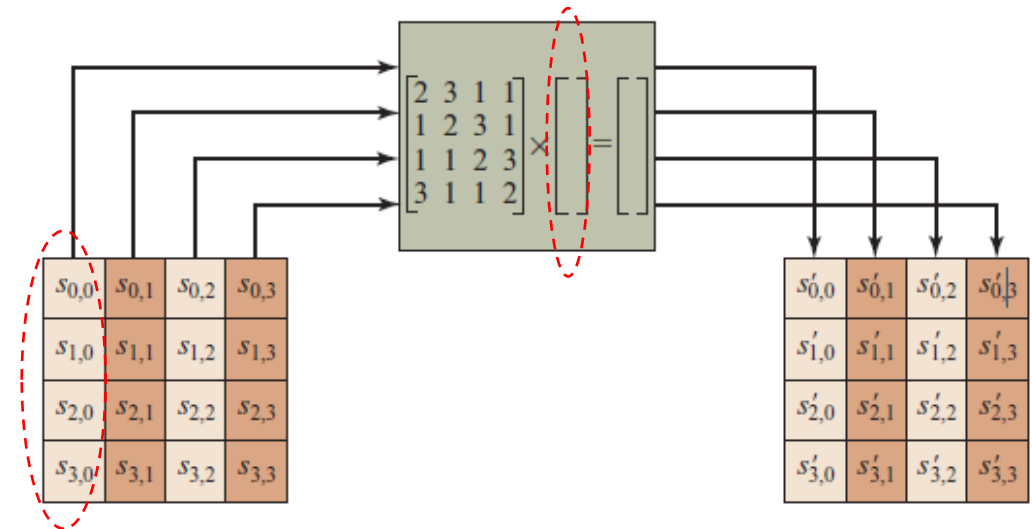

- To move individual bytes from one column to another and spread bytes over columns
- Decryption does reverse
- On encryption **left rotate** each row of State by 0,1,2,3 bytes respectively
- The inverse shift row transformation, performs the **circular right** shifts for each of the last three rows, with a one-byte circular right shift for the second row, and so on.

AES: (3) MixColumns Transformation

- **Mix columns:**
 - Operates on each column individually
 - Mapping each byte to a new value that is a function of all four bytes in the column using of equations over **finite fields in $GF(2^8)$** .
- Coefficients of a matrix based on a linear code with maximal distance between code words ensures a good mixing among the bytes of each column
- The mix column transformation combined with the shift row transformation ensures that after a few rounds all output bits depend on all input bits

$$\begin{bmatrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{bmatrix} \begin{bmatrix} s_{0,0} & s_{0,1} & s_{0,2} & s_{0,3} \\ s_{1,0} & s_{1,1} & s_{1,2} & s_{1,3} \\ s_{2,0} & s_{2,1} & s_{2,2} & s_{2,3} \\ s_{3,0} & s_{3,1} & s_{3,2} & s_{3,3} \end{bmatrix} = \begin{bmatrix} s'_{0,0} & s'_{0,1} & s'_{0,2} & s'_{0,3} \\ s'_{1,0} & s'_{1,1} & s'_{1,2} & s'_{1,3} \\ s'_{2,0} & s'_{2,1} & s'_{2,2} & s'_{2,3} \\ s'_{3,0} & s'_{3,1} & s'_{3,2} & s'_{3,3} \end{bmatrix}$$

$$s'_{0,j} = (2 \cdot s_{0,j}) \oplus (3 \cdot s_{1,j}) \oplus s_{2,j} \oplus s_{3,j}$$

$$s'_{1,j} = s_{0,j} \oplus (2 \cdot s_{1,j}) \oplus (3 \cdot s_{2,j}) \oplus s_{3,j}$$

$$s'_{2,j} = s_{0,j} \oplus s_{1,j} \oplus (2 \cdot s_{2,j}) \oplus (3 \cdot s_{3,j})$$

$$s'_{3,j} = (3 \cdot s_{0,j}) \oplus s_{1,j} \oplus s_{2,j} \oplus (2 \cdot s_{3,j})$$

AES: (3) MixColumns Transformation - Example

02	03	01	01
01	02	03	01
01	01	02	03
03	01	01	02

87	F2	4D	97
6E	4C	90	EC
46	E7	4A	C3
A6	8C	D8	95

47	40	A3	4C
37	D4	70	9F
94	E4	3A	42
ED	A5	A6	BC

$$s'_{0,j} = (2 \cdot s_{0,j}) \oplus (3 \cdot s_{1,j}) \oplus s_{2,j} \oplus s_{3,j}$$

$$s'_{1,j} = s_{0,j} \oplus (2 \cdot s_{1,j}) \oplus (3 \cdot s_{2,j}) \oplus s_{3,j}$$

$$s'_{2,j} = s_{0,j} \oplus s_{1,j} \oplus (2 \cdot s_{2,j}) \oplus (3 \cdot s_{3,j})$$

$$s'_{3,j} = (3 \cdot s_{0,j}) \oplus s_{1,j} \oplus s_{2,j} \oplus (2 \cdot s_{3,j})$$

$$(\{02\} \cdot \{87\}) \oplus (\{03\} \cdot \{6E\}) \oplus \{46\} \oplus \{A6\} = \{47\}$$

$$\{87\} \oplus (\{02\} \cdot \{6E\}) \oplus (\{03\} \cdot \{46\}) \oplus \{A6\} = \{37\}$$

$$\{87\} \oplus \{6E\} \oplus (\{02\} \cdot \{46\}) \oplus (\{03\} \cdot \{A6\}) = \{94\}$$

$$(\{03\} \cdot \{87\}) \oplus \{6E\} \oplus \{46\} \oplus (\{02\} \cdot \{A6\}) = \{ED\}$$

Multiplication of a value by x (i.e., by $\{02\}$) can be implemented as a 1-bit left shift followed by a conditional bitwise XOR with $(0001\ 1011)$ if the leftmost bit of the original value (prior to the shift) is 1.

or do polynomial multiplication mod $m(x) = x^8 + x^4 + x^3 + x + 1$.

$$\{02\} \cdot \{87\} = 0001\ 0101$$

$$\{03\} \cdot \{6E\} = 1011\ 0010$$

$$\{46\} = 0100\ 0110$$

$$\{A6\} = 1010\ 0110$$

$$0100\ 0111 = \{47\}$$

$$\{02\} \cdot \{87\} = (0000\ 0010) \cdot (1000\ 0111)$$

$$= (0000\ 1110) \text{ XOR } (0001\ 1011) = 0001\ 0101$$

$$\begin{aligned} \{x\} \cdot \{x^7 + x^2 + x + 1\} &= (x^8 + x^3 + x^2 + x) \bmod (x^8 + x^4 + x^3 + x + 1) \\ &= x^4 + x^2 + 1 = 0001\ 0101 \end{aligned}$$

AES: (3) Inverse MixColumns Transformation

- The **inverse mix column transformation** is defined by the following matrix multiplication:

$$\begin{bmatrix} 0E & 0B & 0D & 09 \\ 09 & 0E & 0B & 0D \\ 0D & 09 & 0E & 0B \\ 0B & 0D & 09 & 0E \end{bmatrix} \begin{bmatrix} s_{0,0} & s_{0,1} & s_{0,2} & s_{0,3} \\ s_{1,0} & s_{1,1} & s_{1,2} & s_{1,3} \\ s_{2,0} & s_{2,1} & s_{2,2} & s_{2,3} \\ s_{3,0} & s_{3,1} & s_{3,2} & s_{3,3} \end{bmatrix} = \begin{bmatrix} s'_{0,0} & s'_{0,1} & s'_{0,2} & s'_{0,3} \\ s'_{1,0} & s'_{1,1} & s'_{1,2} & s'_{1,3} \\ s'_{2,0} & s'_{2,1} & s'_{2,2} & s'_{2,3} \\ s'_{3,0} & s'_{3,1} & s'_{3,2} & s'_{3,3} \end{bmatrix}$$

- Such that:

$$\begin{bmatrix} 0E & 0B & 0D & 09 \\ 09 & 0E & 0B & 0D \\ 0D & 09 & 0E & 0B \\ 0B & 0D & 09 & 0E \end{bmatrix} \begin{bmatrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

AES: (4) AddRoundKey Transformation

- 128 bits of State are bitwise **XORed** with the 128 bits of the round key

47	40	A3	4C
37	D4	70	9F
94	E4	3A	42
ED	A5	A6	BC

 \oplus

AC	19	28	57
77	FA	D1	5C
66	DC	29	00
F3	21	41	6A

 $=$

EB	59	8B	1B
40	2E	A1	C3
F2	38	13	42
1E	84	E7	D6

- The inverse add round key transformation is identical to the forward add round key transformation, because the XOR operation is its own inverse.

Rationale:

Is as simple as possible and affects every bit of State

The complexity of the round key expansion plus the complexity of the other stages of AES ensure security

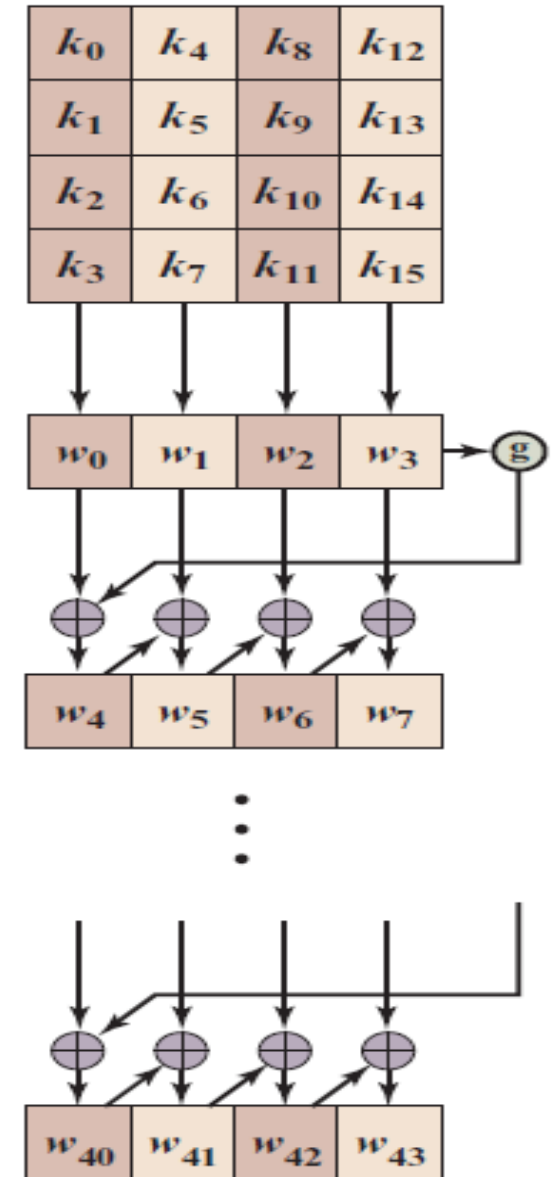

AES Key Expansion

- Takes as input a four-word (16 byte) key and produces a linear array of 44 words (176) bytes
- Key (round 0 key) is copied into the first four words of the expanded key
- The remainder (round 1 to 10) of the expanded key is filled in four words at a time
- Next four *words*:
 - $W[i] = g(w[i-1]) \text{ XOR } w[i-4] \quad \{ \text{if } i \bmod 4 = 0 \}$
 - Else $W[i] = w[i-1] \text{ XOR } w[i-4]$

What is $g()$?

AES Key Expansion – Function $g()$

- The function $g()$ consists of the following subfunctions.

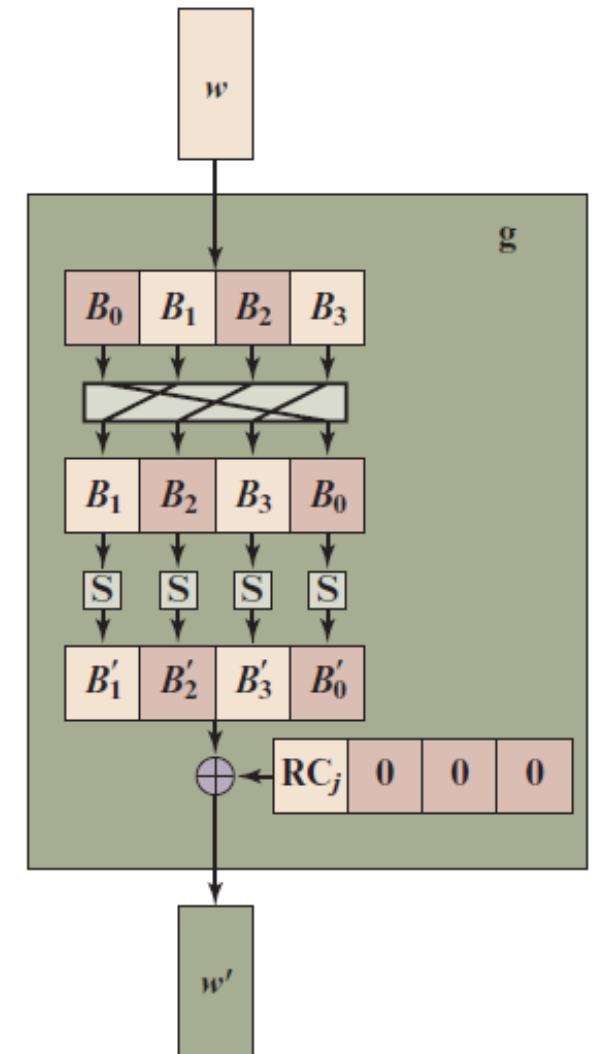

- RotWord** performs a one-byte circular left shift on a word.

Example: Input word $[B_0, B_1, B_2, B_3] \rightarrow$ transformed into $[B_1, B_2, B_3, B_0]$.

- SubWord** performs a byte substitution on each byte of its input word, using the S-box.

- Result of step 2 is **XORed** with a **round constant**, $Rcon[j]$.

AES Key Expansion – Function $g()$

```
KeyExpansion (byte key[16], word w[44])
{
    word temp
    for (i = 0; i < 4; i++)
        w[i] = (key[4*i], key[4*i+1], key[4*i+2], key[4*i+3]);
    for (i = 4; i < 44; i++)
    {
        temp = w[i - 1];
        if (i mod 4 = 0)
            temp = SubWord (RotWord (temp))  $\oplus$  Rcon[i/4];
        w[i] = w[i-4]  $\oplus$  temp
    }
}
```

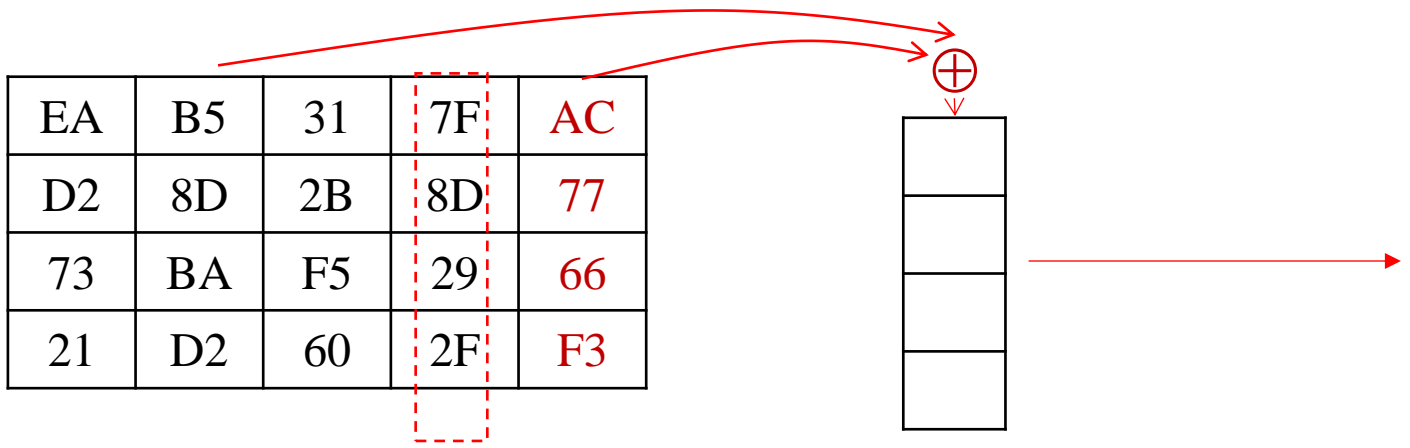

AES Key Expansion – Function $g()$ - Example

If the round key for round 8 is:

EA D2 73 21 B5 8D BA D2 31 2B F5 60 7F 8D 29 2F

What will be the key for round 9:

The first 4 bytes of the key 9 is: $i=36$

i (decimal)	temp	After RotWord	After SubWord	Rcon (9)	After XOR with Rcon	w[i - 4]	w[i] = temp \oplus w[i - 4]
36	7F8D292F	8D292F7F	5DA515D2	1B000000	46A515D2	EAD27321	AC7766F3
